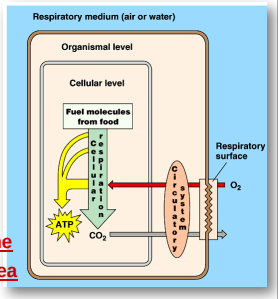
Gas Exchange

- O_2 & CO_2 exchange
  - provides O_2 for aerobic cellular respiration
  - exchange between environment & cells
    - need moist membrane
    - need high surface area

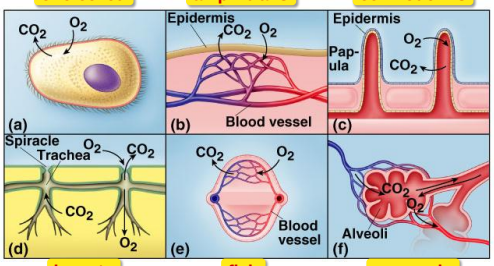


Optimizing Gas Exchange

- Why high surface area?
  - maximizing rate of gas exchange
  - CO_2 & O_2 move across cell membrane by diffusion
    - rate of diffusion proportional to surface area
- Why moist membranes?
  - moisture maintains cell membrane structure
  - gases diffuse only dissolved in water

Gas Exchange in Many Forms…

one-celled | amphibians | echinoderms



insects | fish | mammals

size | water vs. land | endotherm vs. ectotherm

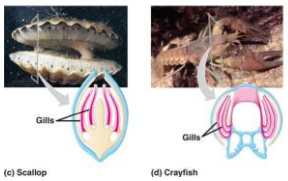
Evolution of Gas Exchange Structures

Aquatic organisms

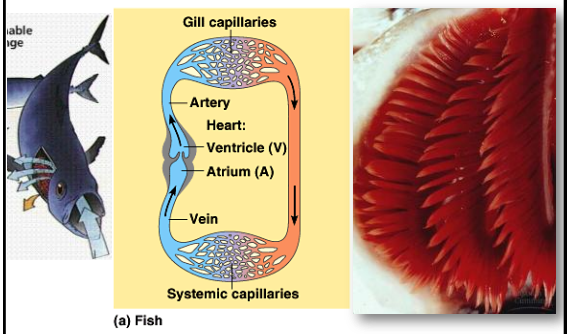
external systems with lots of surface area exposed to aquatic environment

Terrestrial

moist internal respiratory tissues with lots of surface area

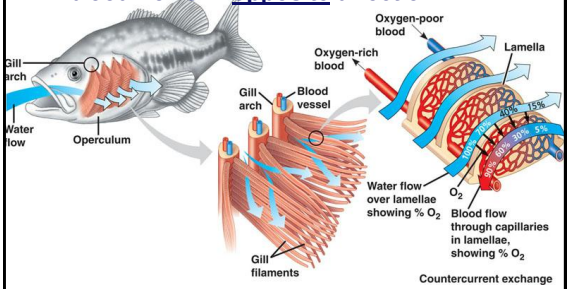


Gas Exchange in Water: Gills

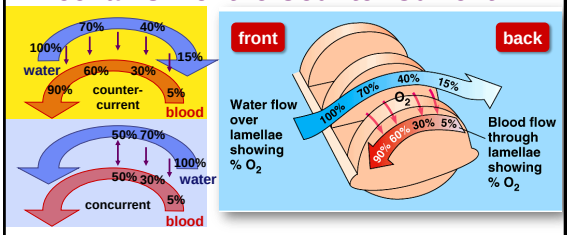


Counter Current Exchange System

- Water carrying gas flows in one direction, blood flows in opposite direction



Mechanism of the Counter Current

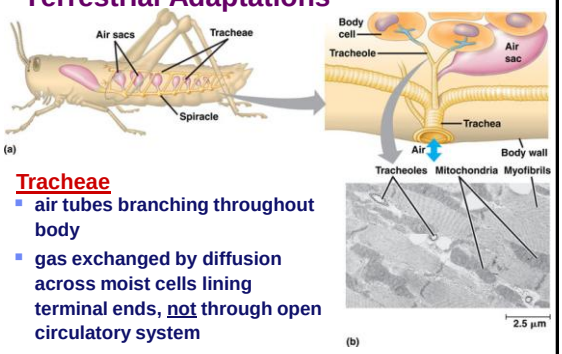


- Blood & water flow in opposite directions
  - maintains diffusion gradient over whole length of gill capillary
  - maximizing O_2 transfer from water to blood

Gas Exchange on Land

- Advantages of terrestrial life
  - air has many advantages over water
    - higher concentration of O_2
    - O_2 & CO_2 diffuse much faster through air
      - respiratory surfaces exposed to air do not have to be ventilated as thoroughly as gills
    - air is much lighter than water & therefore much easier to pump
      - expend less energy moving air in & out
- Disadvantages
  - keeping large respiratory surface moist causes high water loss
    - reduce water loss by keeping lungs internal

Terrestrial Adaptations

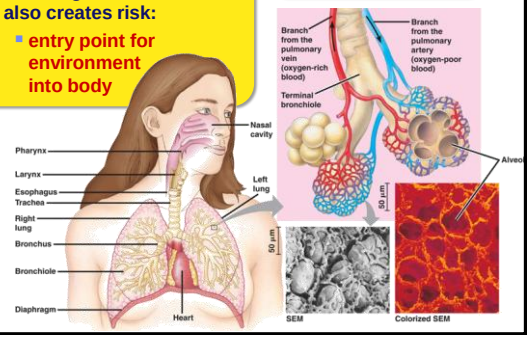


Tracheae
- air tubes branching throughout body
- gas exchanged by diffusion across moist cells lining terminal ends, not through open circulatory system

Lungs

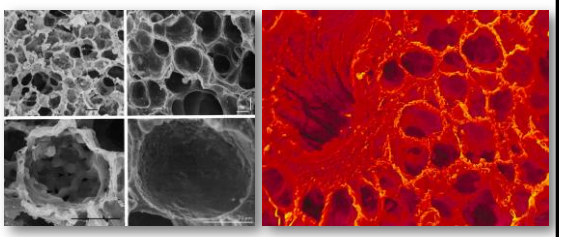
spongy texture, honeycombed with moist epithelium

- Exchange surface, but also creates risk:
  - entry point for environment into body



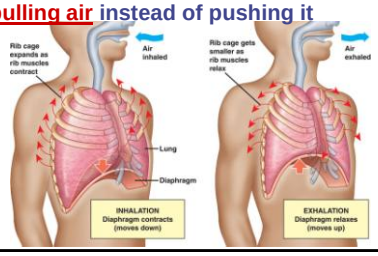
Alveoli

- Gas exchange across thin epithelium of millions of alveoli
  - total surface area in humans ~75 m^2



Negative Pressure Breathing

- Breathing due to changing pressures in lungs
  - air flows from higher pressure to lower pressure
  - pulling air instead of pushing it

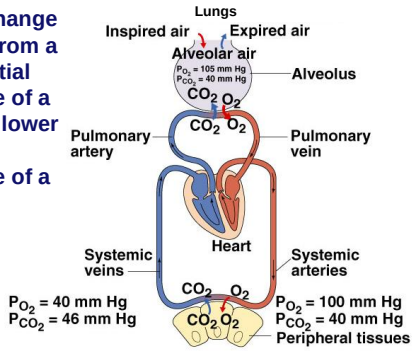


Mechanics of Breathing

- Air enters nostrils
  - filtered by hairs, warmed & humidified
  - sampled for odors
- Pharynx → glottis → larynx (vocal cords) → trachea (windpipe) → bronchi → bronchioles → air sacs (alveoli)
- Epithelial lining covered by cilia & thin film of mucus
  - mucus traps dust, pollen, particulates
  - beating cilia move mucus upward to pharynx, where it is swallowed

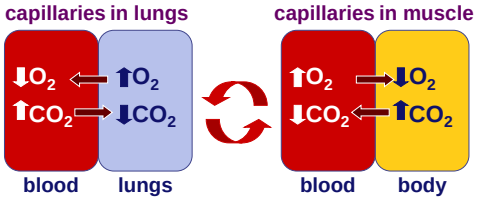
Pressure Gradients

- gas exchange occurs from a high partial pressure of a gas to a lower partial pressure of a gas



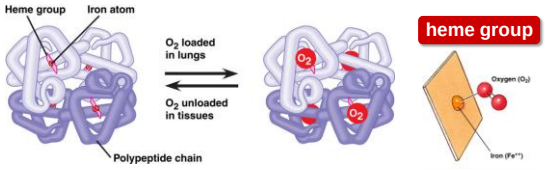
Diffusion of Gases

- Concentration & pressure drives movement of gases into & out of blood at both lungs & body tissue



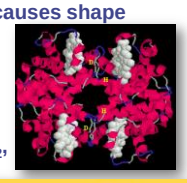
Hemoglobin

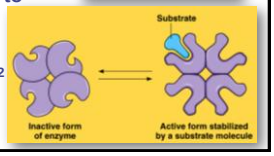
- Why use a carrier molecule?
  - O_2 not soluble enough in H_2O for animal needs
    - blood alone could not provide enough O_2 to animal cells
    - hemocyanin in insects = copper (bluish)
    - hemoglobin in vertebrates = iron (reddish)
- Reversibly binds O_2
  - loading O_2 at lungs or gills & unloading at cells



Cooperativity in Hemoglobin

- Binding O_2
  - binding of O_2 to 1st subunit causes shape change to other subunits
    - conformational change
  - increasing attraction to O_2
- Releasing O_2
  - when 1st subunit releases O_2, causes shape change to other subunits
    - conformational change
  - lowers attraction to O_2



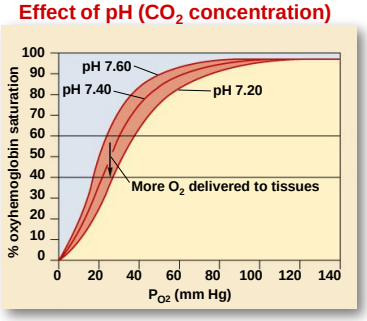


O_2 Dissociation Curve for Hemoglobin

Bohr Shift

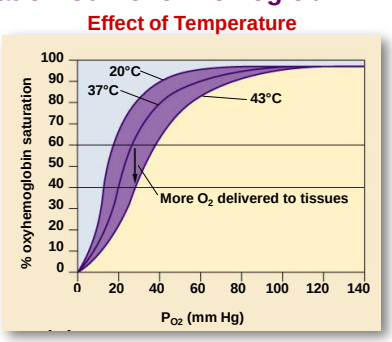
- drop in pH lowers affinity of Hb for O_2
- active tissue (producing CO_2) lowers blood pH & induces Hb to release more O_2

Effect of pH (CO_2 concentration)



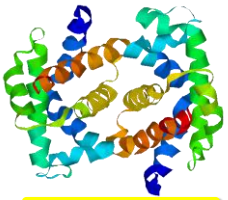
O_2 Dissociation Curve for Hemoglobin

- increase in temperature lowers affinity of Hb for O_2
- active muscle produces heat

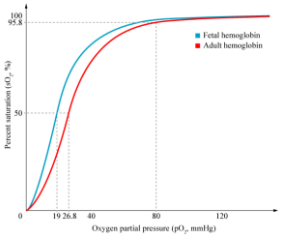


Fetal Hemoglobin (HbF)

- HbF has greater attraction to O_2 than Hb
  - low O_2% by time blood reaches placenta
  - fetal Hb must be able to bind O_2 with greater attraction than maternal Hb



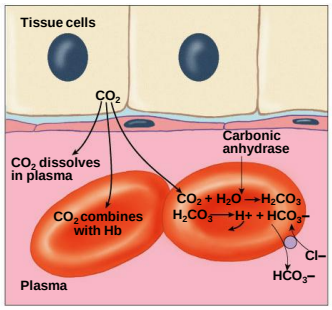
2 alpha & 2 gamma units



Transporting CO_2 in Blood

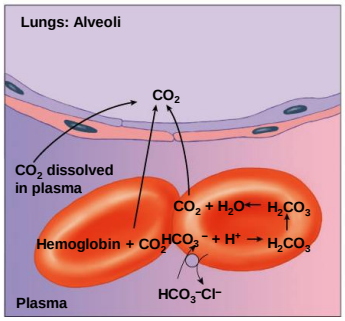
- Dissolved in blood plasma as bicarbonate ion

carbonic acid
$CO_2 + H_2O \rightarrow H_2CO_3$
carbonic anhydrase
bicarbonate
$H_2CO_3 \rightarrow H^+ + HCO_3^-$



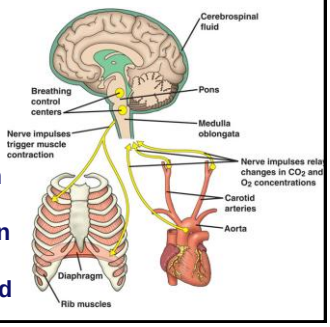
Releasing CO_2 From Blood at Lungs

- Lower CO_2 pressure at lungs allows CO_2 to diffuse out of blood into lungs



Autonomic Breathing Control

- Medulla sets rhythm & pons moderates it
  - coordinate respiratory, cardiovascular systems & metabolic demands
- Nerve sensors in walls of aorta & carotid arteries in neck detect O_2 & CO_2 in blood



Medulla Monitors Blood

- Monitors CO_2 level of blood
  - measures pH of blood & cerebrospinal fluid bathing brain
    - $CO_2 + H_2O \rightarrow H_2CO_3$ (carbonic acid)
    - if pH decreases then increase depth & rate of breathing & excess CO_2 is eliminated in exhaled air
